A heterogeneous vehicle routing problem with drones and multiple depots

Panagiotis Zachos

June 2024

1 Στόχος

Επέκταση του mixed fleet capacitated multiple TSP (mfcmTSP) (Oikonomou et al. 2019) όπου ένα φορτηγό με απεριόριστη χωρητικότητα, μία μοτοσυκλέτα με αυθαίρετη χωρητικότητα και ένα drone με χωρητικότητα 1, πρέπει να επισκεφτούν πελάτες, οι οποίοι έχουν ζήτηση 1 δέμα ο καθένας, στον μικρότερο δυνατό χρόνο.

Κύρια χαρακτηριστικά του νέου προβλήματος (Multi-Depot mfcmTSP):

- Ανάθεση χωρητικότητας στα φορτηγά (έναντι απεριόριστης).
- Οι μοτοσυκλέτες μπορούν να επισκεφτούν όλους τους πελάτες.
- Τα φορτηγά μπορούν να επισκεφτούν μερικούς πελάτες μόνο, λόγω μεγάλου μεγέθους (στενοί δρόμοι, σοκάκια) (~90%).
- Τα drones μπορούν να επισκεφτούν μερικούς πελάτες μόνο, λόγω ακατάλληλων συνθηκών προσγείωσης ή λόγω προτίμησης πελατών (~85%).
- Πολλαπλές αποθήκες (>1), με την κάθε αποθήκη να διαθέτει τον δικό της στόλο οχημάτων. Συγκεκριμένα, η κάθε αποθήκη μπορεί να έιναι εξοπλισμένη με [1,∞] φορτηγά, [0,∞] μοτοσυκλέτες και [0,∞] drones. Ωστόσο, τουλάχιστον μία αποθήκη θα πρέπει να εμπεριέχει στον στόλο της τουλάχιστον μία μοτοσυκλέτα έτσι ώστε να μπορούν να εξυπηρετηθούν όλοι οι πελάτες.

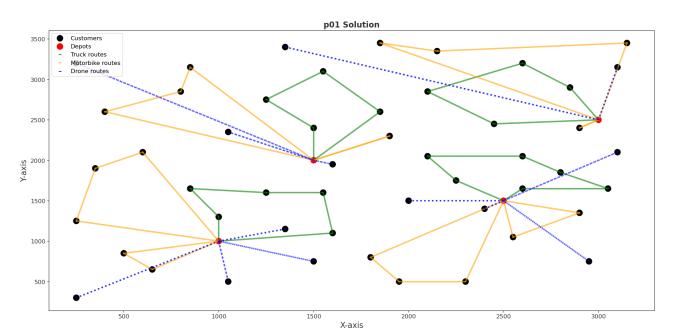

Figure 1: Solution example with 50 customers and 4 depots

2 Περιεχόμενα

- Υλοποίηση του mfcmTSP (2019) heuristic, με προσθήκη υποστήριξης πολλαπλών οχημάτων κάθε είδους σε κάθε αποθήκη, και χρήση τεχνικής cluster first-route second για την προσαρμογή του αλγορίθμου στην εκδοχή του προβλήματος με πολλαπλές αποθήκες.
- Βελτίωση του αλγορίθμου και σύγκριση αποτελεσμάτων.
- Χρήση local search optimization για την περαιτέρω βελτίωση αποτελεσμάτων.
- Παρουσίαση ενός υβριδιχού metaheuristic που κάνει χρήση του Ant Colony Optimization σε συνδυασμό με το heuristic.
- Σύγκριση των αλγορίθμων.

2.1 Motivation / Use case

Consider a parcel delivery company operating in Greece, with depots located in two major cities: Athens and Thessaloniki. The company manages numerous last-mile delivery shops in these cities, which serve as depots in the routing problem. For instance, a customer in Thessaloniki sends a parcel to a friend in Athens by visiting a nearby shop. After the shop stops receiving parcels for the day, a truck collects the parcels and delivers them to the Thessaloniki distribution center. Parcels destined for Athens are then transported overnight to the Athens distribution center. Upon arrival, parcels are sorted based on their delivery areas and sent to the appropriate last-mile shops in Athens. These shops, acting as depots in our problem, dispatch vehicles (Trucks, Motorbikes, Drones) to deliver the parcels to their final destinations. The MD-mfcmTSP addresses how these vehicles can be optimally routed to minimize delivery time, while simultaneously solving the problem of parcel allocation in each last-mile shop.

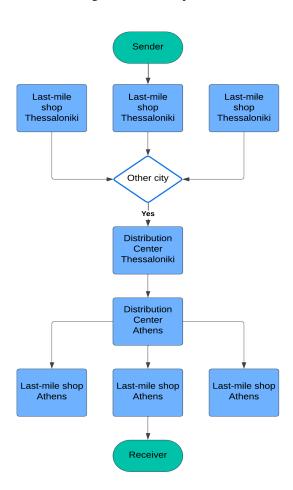

Figure 2: Life of a parcel

3 Objective

The objective of the MD-mfcmTSP is to minimize the total makespan in which all customers are visited/served i.e min M_{total} .

Notation

- *m* : Number of depots
- D : Set of depots
- R_T^i : Truck route of depot $i \in D$
- R_M^i : Motorbike route of depot $i \in D$
- R_D^i : Drone route of depot $i \in D$
- M_T^i : Time of the Truck's route(s) $(N_T^i = 1)$ or Makespan of the Trucks' route(s) $(N_T^i > 1)$ of depot $i \in D$
- M_M^i : Time of the Motorbike's route(s) $(N_M^i = 1)$ or Makespan of Motorbikes' route(s) $(N_M^i > 1)$ of depot $i \in D$
- M_D^i : Time of the Drone's route(s) $(N_D^i=1)$ or Makespan of Drones' route(s) $(N_D^i>1)$ of depot $i\in D$
- $M_{total}^i = max(M_T^i, M_M^i, M_D^i)$: Makespan of depot $i \in D$
- $M_T = max(M_T^i, M_T^{i+1}, ..., M_T^m)$: Makespan of Trucks
- $M_M = max(M_M^i, M_M^{i+1}, ..., M_M^m)$: Makespan of Motorbikes
- $M_D = max(M_D^i, M_D^{i+1}, ..., M_D^m)$: Makespan of Drones
- $M_{total} = max(M_T, M_M, M_D)$: Total makespan
- $M_{total} = max(M_{total}^i, M_{total}^{i+1}, ..., M_{total}^m)$: Total makespan

Table 1: Example

Depot	M_T	M_M	M_D	Depot makespan
1	3	2	1	3
2	4	3	2	4
3	1	5	2	5
4	2	8	1	8
$\overline{M_{total}}$	4	8	2	8

3.1 Makespan calculations

In the case where a depot is equipped with more than 1 vehicle of any type (excluding vehicles with capacity = 1 i.e drones), and two or more routes need to be assigned to them, a **job scheduling problem** arises, where the routes are the jobs that need to be assigned to machines (vehicles). Since the vehicles are identical, it's more specifically an **identical-machines scheduling problem**. Minimizing the maximum completion time (makespan) is NP-hard. Many exact and approximation algorithms are known. We use the **longest-processing-time-first** (**LPT**) greedy algorithm, which orders the jobs by descending order of their cost and then schedules each job in this sequence into the machine of which the current load is smallest. An example is given below. Assume 4 routes that need to be assigned to two trucks. Each route has a time cost associated with it. The route assignment needs to be done in such a way that the trucks' makespan is minimized. We first sort the routes based on their cost in a descending order. Then, starting from the route with the maximum cost, we assign it to the truck with the currently minimum makespan. This is done iteratively until all routes have been assigned to a vehicle.

Table 2: 4 routes that need to be assigned to a depot's 2 trucks

Route	Cost
1	5
2	6
3	2
4	3

Procedure for the assignment of 4 routes to 2 trucks of the same depot:

Table 3: Sort routes in descending order based on cost

Route	Cost
2	6
1	5
4	3
3	2

Table 4: Iteratively assign routes to Trucks

Iteration	Route	Cost	Truck	Truck 1 ms	Truck 2 ms			
1	2	6	1	6	0			
2	1	5	2	6	5			
3	4	3	2	6	8			
4	3	2	1	8	8			
Total makespan = 8 (optimal)								

Pseudocode MD-mfcmTSP for the heuristic

Algorithm 1: MD-mfcmTSP heuristic

```
Input: G_T, G_M, ..., G_D
    Output: M_{total},
               Sol = \{Sol^i = \{R_T^i, R_M^i, ..., R_D^i\}, Sol^{i+1}, ..., Sol^m\} \text{ for }

5 Solving the MD-mfcmTSP

In this section, we introduce the two algorithmic approaches to address the MD-mfcmTSP. The first approach which is used to tackle the problem comprises of a clustering phase, which transforms the multi-depot problem into multiple single-depot mfcmTSP problems, and a routing phase which calls the mfcmTSP heuristic for each depot. The second approach leverages a hybrid metaheuristic, combining Ant Colony Optimization (ACO) with the mfcmTSP heuristic.

5.1 MD-mfcmTSP heuristic

To manage the complexity of multi-depot routing problems, a widely used approach is their transformation to multiple single-depot routing problems. Although a naive approach, it provides feasible solutions of which the results are used as a baseline for comparison with other solution methods.

For this purpose, we use a straightforward constrained proximity clustering to assign customers to depots, and then run the mfcmTSP heuristic for each depot. Each customer is assigned to the closest *possible* depot, creating clusters where each depot serves the customers nearest to it. Specifically, vehicle availability at each depot may limit the customers that are assigned to its cluster. The reason is that the initialization phase of the heuristic, which is based on these clusters, must form routes that visit every node $c_i \in C$. Therefore, while the assignment is based on proximity, we must adjust the clustering to account for these constraints. This means that some customers may need to be assigned to a more distant depot if the nearest depot lacks the vehicle that can serve them. For example, a customer only accessible by motorbike will be assigned to a more distant depot when the closest to them doesn't have a motorbike available in its fleet.

Figure 3: Initialization example

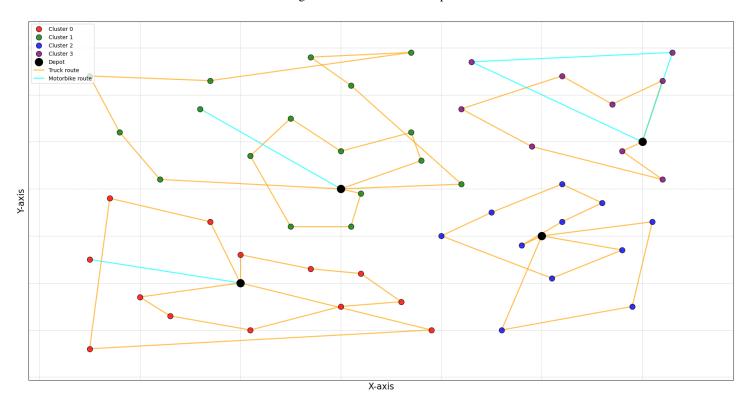

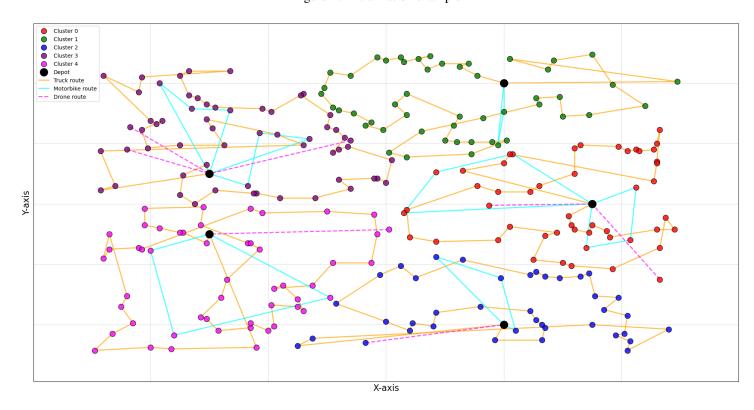

Figure 4: Initialization example

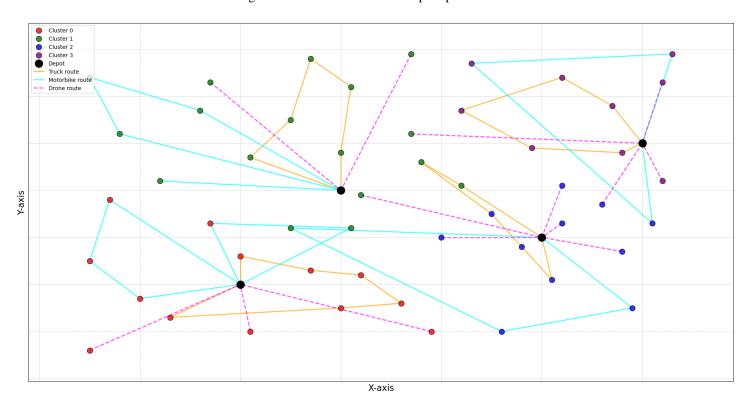

Figure 5: Solution after mutual depot optimization

5.2 Hybrid Ant Colony Optimization

For the second approach to solve the MD-mfcmTSP we introduce a novel hybrid metaheuristic based on the principles of Ant Colony Optimization combined with the mfcmTSP heuristic. Specifically, we employ a modified version of the Adaptive Ant Colony Optimization with Node Clustering (AACONC) (Stodola et al. 2022) which was developed for the Multi-Depot Vehicle Routing Problem and showed promising results. From now on, we refer to this algorithm as the H-AACONC.

5.2.1 H-AACONC Algorithm

The Ant Colony part of the algorithm disregards accessibility constraints and assumes that all customers must be served by trucks such as to minimize the total time (makespan). As such, the pheromone matrix, node clustering and the AntSolution function remain the same as in AACONC and are used to create an initial trucks-only solution which is stored in Rt. Then, with frequency n_{freq} , which is one of the AACONC control parameters, the single and mutual colony local optimization procedures may be called. In the resulting solution Rt, customers that are not accessible by trucks are then offloaded to the motorbike(s) of the same depot if possible, else to the closest depot with atleast one motorbike in its fleet. The resulting routes are inserted into R_{best} and the MD-mfcmTSP heuristic is called, while skipping the clustering and initialization phase.

5.2.2 Pheromone matrix update

One key distinction between the AACONC and the H-AACONC is the pheromone matrix update procedure. The pheromone matrix update procedure uses the same logic as the AACONC. The Simulated Annealing principle in combination with the Metropolis criterion probabilistically decide which solution will be used for the update. Although in the H-AACONC, while solutions R and R_{best} are used to make this decision, it is then truck solutions Rt and Rt_{best} respectively that are used to update the pheromone matrix.

$$p(R^{best}) = 1 - p(R) = \begin{cases} e^{-\frac{(|R^{best}| - |R|)/|R|}{T_{update}}} & \text{for } |R^{best}| > |R|, \\ 1 & \text{otherwise} \end{cases}$$
(1)

$$T_{\text{update}}(iter + 1) = \alpha_{\text{update}} \cdot T_{\text{update}}(iter)$$
 (2)

The solution for updating the pheromone matrix R^{update} is selected based on the calculated probabilities: $R^{update} = R^{best}$ and $Rt^{update} = Rt^{best}$ with $p(R^{best})$ or $R^{update} = R$ and $Rt^{update} = Rt$ with $p(R) = 1 - p(R^{best})$. The update itself is then conducted using (3); the pheromone trails lying on the routes are increased in proportion to the pheromone updating coefficient δ and the quality of the updating route (a ratio of R to R^{update}).

$$\tau_{ij}^{k} = \tau_{ij}^{k} + \chi_{ij} \cdot \delta \cdot \frac{|R|}{|R^{update}|} \text{ for all } v_i, v_j \in V \text{ and } d_k \in D$$
 (3)

$$\chi_{ij} = \begin{cases} 1 & \text{if there is an edge between } v_i \text{ and } v_j \text{ in } Rt^{update}, \\ 0 & \text{otherwise} \end{cases}$$
 (4)

Algorithm 7: Hybrid AACONC

```
Input: G_T, G_M, ..., G_D
   Output: M_{total},

7 Results

7.1 New heuristic vs original heuristic

mfcmTSP heuristic (original): Finds and swaps the minimum cost route in each iteration

MD-mfcmTSP heuristic (v1): Finds and swaps the route which minimizes the depot's makespan in each iteration

Results show that the new (v1) heuristic performs better than the original.

        iter += 1
29
```

9.1 Pheromone matrix & update

30 end while

Στον αλγόριθμο AACONC (Stodola, 2022), ο πίναχας φερομόνων χρησιμοποιείται για την εύρεση μιας ολοχληρωμένης λύσης για το πρόβλημα MDVRP. Στον αλγόριθμο (Hybrid AACONC) ο πιναχας φερομόνων χρησιμοποιείται για την εύρεση λύσης Rt_{best} , που δεν αποτελεί τελιχή λύση του προβλήματος, αλλά μια αρχιχή (συνήθως ανέφιχτη) λύση. Η ενημέρωση του πίναχα φερομόνων χρησιμοποιεί την αρχή της προσομοίωσης ανόπτησης (simulated annealing). Συγχεχριμένα, χρησιμοποιείται το Metropolis criterion για να αποφασιστεί αν θα χρησιμοποιηθεί η καλύτερη λύση που έχει βρεθεί ως τώρα (R) ή η λύση της τωρινής γενιάς (R_{best}) . Αν η τωρινή γενιά βελτιώνει το αποτέλεσμα, τότε αυτή πάντα αντιχαθιστά την καλύτερη λύση $(R=R_{best})$ και χρησιμοποιείται για την ενημέρωση. Όμως υπάρχει πιθανότητα να επιλεχθεί αχόμα και αν είναι χειρότερη από την μέχρι τώρα καλύτερη λύση. Αυτό βοηθάει στη διατήρηση της ποιχιλομορφίας του πληθυσμού, επεχτείνοντας έτσι τον χώρο αναζήτησης (search space) και αποτρέποντας τον αλγόριθμο από το να βρεθεί σε τοπιχό βέλτιστο (local optima). Είναι σημαντιχό να σημειωθεί, οτι ενώ η επιλογή της λύσης βάση της οποίας θα ενημερωθεί ο πίναχας φερομόνων εξαρτάται από τα R, R_{best} , τα δρομολόγια τα οποία χρησιμοποιούνται για την ενημέρωση είναι αυτά των Rt, Rt_{best} αντίστοιχα. Επομένως, στο AACONC(MDVRP) καθώς και σε αυτόν τον αλγόριθμο, ο πίναχας φερομόνων έχει σημαντικό ρόλο, στον τελευταίο χρησιμοποιείται για την παραγωγή μίας αρχικής λύσης ενώ στον πρώτο για την παραγωγή μιας ολοκληρωμένης λύσης.

10 Related Literature

At the same time, it is important that we address flight range limitations. Such limitations have important roles in much of the existing drone routing research. However, even he first drones developed by Amazon and JD.com ahad a flight range of 15 to 20 miles [33, 56]. Such a range is suitable to allow out and back travel in the medium-sized cities in which the authors live, Braunschweig, Germany, and Iowa City, United States. In fact, it is suitable for many larger cities such as Hamburg, Munich, and Paris. Thus, in contrast to other drone applications, in this work, we do not consider flight range as a limiting factor (Ulmer & Thomas (2018)).
